API Design

Application programming interface:

response → List <Admin> admins

group Service

1. Naming

2. Parameters

3. Response output.

Set admins (List <Admin> admins, String groupId)

T209

Your API should have no side effects.

Doing Everything in one function.

"API" : "big bang"

Atomicity: means that operations must complete or fail as a whole unit.

on Database level we use transactions - you wrap multiple

Pagination: operations in a transaction. If anything fails everything goes back to the original state.

in API level, Developers design endpoints. So that each request contained a self-contained action.

Atomicity is actual one of four ACID properties. Atomicity, consistency, Isolation, Durability.

Pagination:

Is the practice of splitting a large set of results into smaller chunks. Instead of returning everything at once.

why it needed:

if a API that returns all users from a database that has 1 million records. Sending all of them in one response would be extremely slow

use massive memory and likely crash the client, pagination solves this by delivering data into manageable pieces.

' Fragmentation : In APIs, refer to breaking a response into smaller, selective pieces, so the client get only the data it actually needs rather than receiving the entire resource.
